Welcome to the **SoftHSM** site for the **OpenDNSSEC** Project!!

SoftHSM is an implementation of a cryptographic store accessible through a PKCS#11 interface. You can use it to explore PKCS#11 without having a Hardware Security Module. It is being developed as a part of the OpenDNSSEC project.

- [SoftHSM v2](#)

Background

OpenDNSSEC handles and stores its cryptographic keys via the PKCS#11 interface. This interface specifies how to communicate with cryptographic devices such as HSM:s (Hardware Security Modules) and smart cards. The purpose of these devices is, among others, to generate cryptographic keys and sign information without revealing private-key material to the outside world. They are often designed to perform well on these specific tasks compared to ordinary processes in a normal computer.

A potential problem with the use of the PKCS#11 interface is that it might limit the wide spread use of OpenDNSSEC, since a potential user might not be willing to invest in a new hardware device. To counter this effect, OpenDNSSEC is providing a software implementation of a generic cryptographic device with a PKCS#11 interface, the SoftHSM. SoftHSM is designed to meet the requirements of OpenDNSSEC, but can also work together with other cryptographic products because of the PKCS#11 interface.

SoftHSM v1

The first version of [SoftHSM](#) was developed for OpenDNSSEC using the general requirements for DNSSEC. It uses the library Botan for the crypto operations and the keys are stored in a database backend using SQLite.

Visit the [SoftHSM v1](#) page for more information.

SoftHSM v2

It focuses on a higher level of security by encrypting sensitive information and using unswappable memory. There is also a more generalized crypto backend, where you can use Botan or OpenSSL. Visit the [SoftHSM v2](#) page for more information.
